FARM NUMBERS AND THEIR IMPLICATIONS

FOR ECONOMIC ANALYSIS*

B. F. Stanton

Data on farm numbers are widely discussed and frequently misinterpreted. These numbers comprise one of the nation's oldest and most basic statistical series. As such they are a fundamental part of our agricultural data system. This paper argues that farm numbers should be subdivided into at least two or three separate series for both descriptive and analytical purposes. Such divisions will allow us to better understand the changes in farms and farming which have occurred and the implications of changes now in process. Rates of change in size distributions, productivity and net income can be examined in fuller perspective. Public understanding of the policy issues involved should be enhanced.

These suggestions are made in setting of budget constraints at every level of government. Our national agricultural data system is being asked to establish priorities and reduce expenditures. The Statistical Reporting Service has recently announced that 26 of its reports will be eliminated in 1982; reductions in the number of individual state estimates included in continuing reports will be instituted; the frequency of some reports will be cut.

Analytical work in agricultural economics relies on continuing data series of dependable quality and accuracy. The Economic Statistics Committee of our national association has been active in reviewing components of our

* Invited paper presented at the Northeast Agricultural Economics Council meetings, Burlington, Vermont, June 21-23, 1982. The review and comments of N. L. Bills, J. R. Brake, O. D. Forker, R. B. How and W. G. Tomek are gratefully acknowledged.

national system and making positive suggestions for some improvements (1, 6, 8, 16, 18). Important changes in the measurement of productivity and agricultural income resulted in part from their efforts (13, 15). This productive interchange continues. Both the regional associations and AAEEA, as well as individual economists, must continue to ask questions and invest time in helping to improve our data systems.

Just 10 years ago the Economic Statistics Committee (1) argued that "...the farm or firm as the basic unit of observation from which all food and fiber statistics are constructed is conceptually obsolete" (p. 868). That view has not been generally accepted. To the contrary, farms are still the basic production units of the world's agriculture. Land, labor, capital, and management are combined in producing units out of which crop and live-stock products result. While the ownership and control of some of the resources like land and capital has become more complex, and the identity of the true decision makers with respect to production is sometimes difficult to establish, primary production units, called farms, are almost universally recognized in every language and political system. Thus, attempts to clarify changes in farm numbers seem justified.

Census Definitions and Numbers

Ever since the national census included comprehensive data on farming for the first time in 1840, almost every unit that produced agricultural products beyond a family garden has been counted as a farm. The definition in 1850 essentially set the pattern to the present time:

The returns of all farms and plantations, the produce of which amounts to \$100 in value, are to be included in this schedule; but it is not intended to include the returns of small lots, owned or worked by persons following mechanical or other pursuits, where the productions are not \$100 in value.

Apparently, our national policy over the years has been to make the count of farms as large as possible. Almost any residential unit with some livestock or a crop of some kind has been counted as a farm. As the nation expanded its boundaries, so did the land devoted to agriculture and the number of producing farms. The details of definitions changed nine times from 1850 to 1978, but the underlying concept did not. Currently any producing unit from which \$1,000 or more of agricultural products were sold or normally would have been sold qualifies as a farm.

Farm numbers reached a peak in the United States in the 1930's. After World War II numbers decreased rapidly and average farm size measured in acres increased accordingly. Essentially from 1900 to 1945 farm numbers were stable enough in total that the decreases in one section of the United States were balanced by new farms in another region. Many significant changes occurred between 1910 and 1940 as tractor and machine power replaced horses and hand labor, but the aggregate numbers tended to mask the dimensions of change until off-farm jobs, farm consolidation and new technology reduced the numbers after World War II (Figure 1).

Further Classification

In my view it is not the underlying concept of a farm as a producing unit which is obsolete. Rather it is the desire to include every business unit which produces something in one general classification that is a problem. Two steers on a five acre parcel have little in common with a 500,000 acre cattle ranch. Perhaps both units can be broadly described as farms. But for any kind of analysis or for historical description as well, further separation is necessary.

Figure 1. Numbers of farms, United States, Census data, 1850-1978

It is important to separate the primary producing units or full-time, commercial farms from other units both for description and analysis. Part-time farms include a wide range of situations from those getting started in farming at one end of the spectrum to those who have retired on a small farm at the other. Careful classification of our part-time farms into meaningful groups is necessary as well. The emphasis throughout these comments remains on the producing unit or farm, not on the operator, the business arrangement, or the form of ownership. Output from the unit and the nature of resources employed are much more central to classification.

The United States, so often a leader in agricultural statistics, has been a laggard in developing consistent definitions and data sets for full-time and part-time farms. During the last 30 years the most common classification of farms has been into size groups based either on acres of land or the value of agricultural products sold. Comparing farms on the basis of land area works well when the resource base and type of farming is similar. But for a very large and diverse country classifications on the basis of acreage have little meaning. A cattle ranch of 3,000 acres may barely support one family, while an intensive fruit farm of 50 acres may support two.

Classifications based on agricultural sales have two major problems. Comparisons through time are confounded when inflation or changes in price level become important. Moreover, changes in technology bring with them increased dependence on purchased inputs and increased productivity. Output per worker and per acre increase accordingly. Meaningful comparisons of changes in American agriculture since 1950 are confused by both of these problems.

Some Alternative Definitions

It is easier to identify problems than to offer positive solutions. One approach is to look at what has been done in the past to classify farms into meaningful groups. These procedures can then be adapted to available data for the United States for the years after World War II when farm numbers declined, commercial farming was consolidated into larger units, and technology and prices changed rapidly. The economic classes developed for the agricultural censuses between 1950 and 1969 are one such approach (4). Japanese classifications of full-time and part-time farms are another (9, 10). The AAEA definition of a commercial farm developed in 1919 is still another (7).

Census definitions - In the two decades between 1950 and 1969 the census divided farms into economic classes. In 1950 the two general categories were commercial farms and other. The primary basis for classification was value of farm products sold. Further subdivision of the 44 percent of the total number of farms that had sales of \$1200 or less was on days of work off the farm by the operator and the importance of off-farm income sources (Table 1). Other farms were divided into part-time and residential.

By 1969 the general classification, commercial, was dropped. The value of sales for each of the six classes had been increased. Age as well as days worked off-farm had been included as part of the classification system for part-time farms (Table 2). A general division between farms with sales over \$2,500 and less than \$2,500 was followed in many sections of the summary report. This same practice was continued in the 1974 and 1978 census. Economic classes as such were dropped.

Summary of census statistics 1950-1978 - If a summary of the census data on number of farms by economic class is made between 1950 and 1978 important adjustments are required. While the basis for such adjustments may be challenged, the resulting comparisons provide additional insights into the kinds of change which have occurred over the past 30 years. The census itself made one such set of adjustments relating value of sales to economic class between 1950 and 1959. Prices almost doubled between 1969 and 1978. The Producer Price Index for Industrial Commodities was 106 in 1969 and 209.4 in 1978. Each of the 1969 sales classes were advanced one category for comparability with 1978 (Table 3).

Table 1. DISTRIBUTION OF FARMS BY ECONOMIC CLASS
Census of Agriculture, United States, 1950

Class	Criteria used:		Number of farms
	Value of farm products sold	Other	
<u>Commercial:</u>			
I	\$25,000 and over	None	103,231
II	10,000 - 24,999	None	381,151
III	5,000 - 9,999	None	721,211
IV	2,500 - 4,999	None	882,302
V	1,200 - 2,499	None	901,316
VI	250 - 1,199	Less than 100 days of work off-farm by operator; income of family members from off-farm sources less than value of farm products sold	<u>717,201</u> 3,706,412
<u>Other:</u>			
Part-time	\$250 - 1,199	100 days or more of off-farm work by operator; income of family members from off-farm sources greater than value of farm products sold	639,230
Residential	Less than \$250	None	1,029,392

One can get some further perspective on the changing importance of different classes of farms if one examines the proportion of the nation's agricultural sales contributed by each group in each of the census years. Clearly the largest commercial or full-time farms have provided an increasing proportion of agricultural output. Part-time farms produce a shrinking share of total sales (Table 4).

The three general headings in Table 4 reflect the biases and knowledge of the author from a perspective of the 1980's. Study of the table and the changing proportions must recognize that the definitions of economic classes changed between 1954 and 1959 and again between 1969 and 1978. One such adjustment was made by the Bureau of the Census, the other by the author.

If only the three economic classes with the largest agricultural sales are considered as full-time or commercial farms in 1978 or 1969, there should be little cause for argument. To generate \$10,000 of agricultural sales in 1969 would have required a minimum of 10 to 15 average dairy cows and associated cropping activities. The same number of cows would have generated \$20,000 in 1978. From 50 to 100 acres of field crops would have provided enough sales

to make the minimum of a class 3 farm both years. By the technology standards of these years such a unit was most likely to be a part-time farm and provided much less than full-time work for one individual. In 1950 levels of mechanization and labor productivity were quite different. To have agricultural sales of \$5,000 would have required 10 to 15 cows depending on production levels. Without a milking machine and using horse drawn field equipment, this might have provided almost a full-time job for a modest farm operator. But there were quite a few individuals and families who fitted this description. By 1959 most dairy farms of this size had been mechanized or were on their way out of business. But nationally crop farms with gross sales of \$10,000 from 100 acres of field crops or its equivalent were still fairly common.

A summary of the number of farms in each of the census years divided into three general categories as described in Tables 3 and 4 is presented in Figure 2. The most substantial decrease in numbers between 1950 and 1978 was in part-time and residential farms. The total value of agricultural sales in any of these years was less than the wages of a farm worker and certainly not enough to provide more than a small portion of the living requirements for a farm family. Over the three decades the number of these farms dropped from about 2.4 million in 1950 to less than 1.0 million in 1978.

In contrast the number of commercial farms (classes 1-3) were much more stable, moving from 1.2 million in 1949 down to almost 0.9 million in 1978. For those who want to include class 4 farms in this commercial group the equivalent numbers would then be 2.1 million in 1949 and 1.2 million in 1978. Class 4 and 5 farms in 1969 or 1978 would not have produced enough value added regardless of the type of farming to provide an acceptable living for a farm family. In this sense they are truly part-time farms. These families

Figure 2. Decreases in farm numbers by Economic Class of Farm, United States, 1949 - 1978

are either dependent on off-farm earnings for an important part of their livelihood or else are retired couples living on their savings and social security supplemented with some farm income.

A similar summary of changes in farm numbers between 1949 and 1978 for the 12 northeastern states is presented in Figure 3. About 10 percent of the nation's farms were located in this region in 1949 and a little less

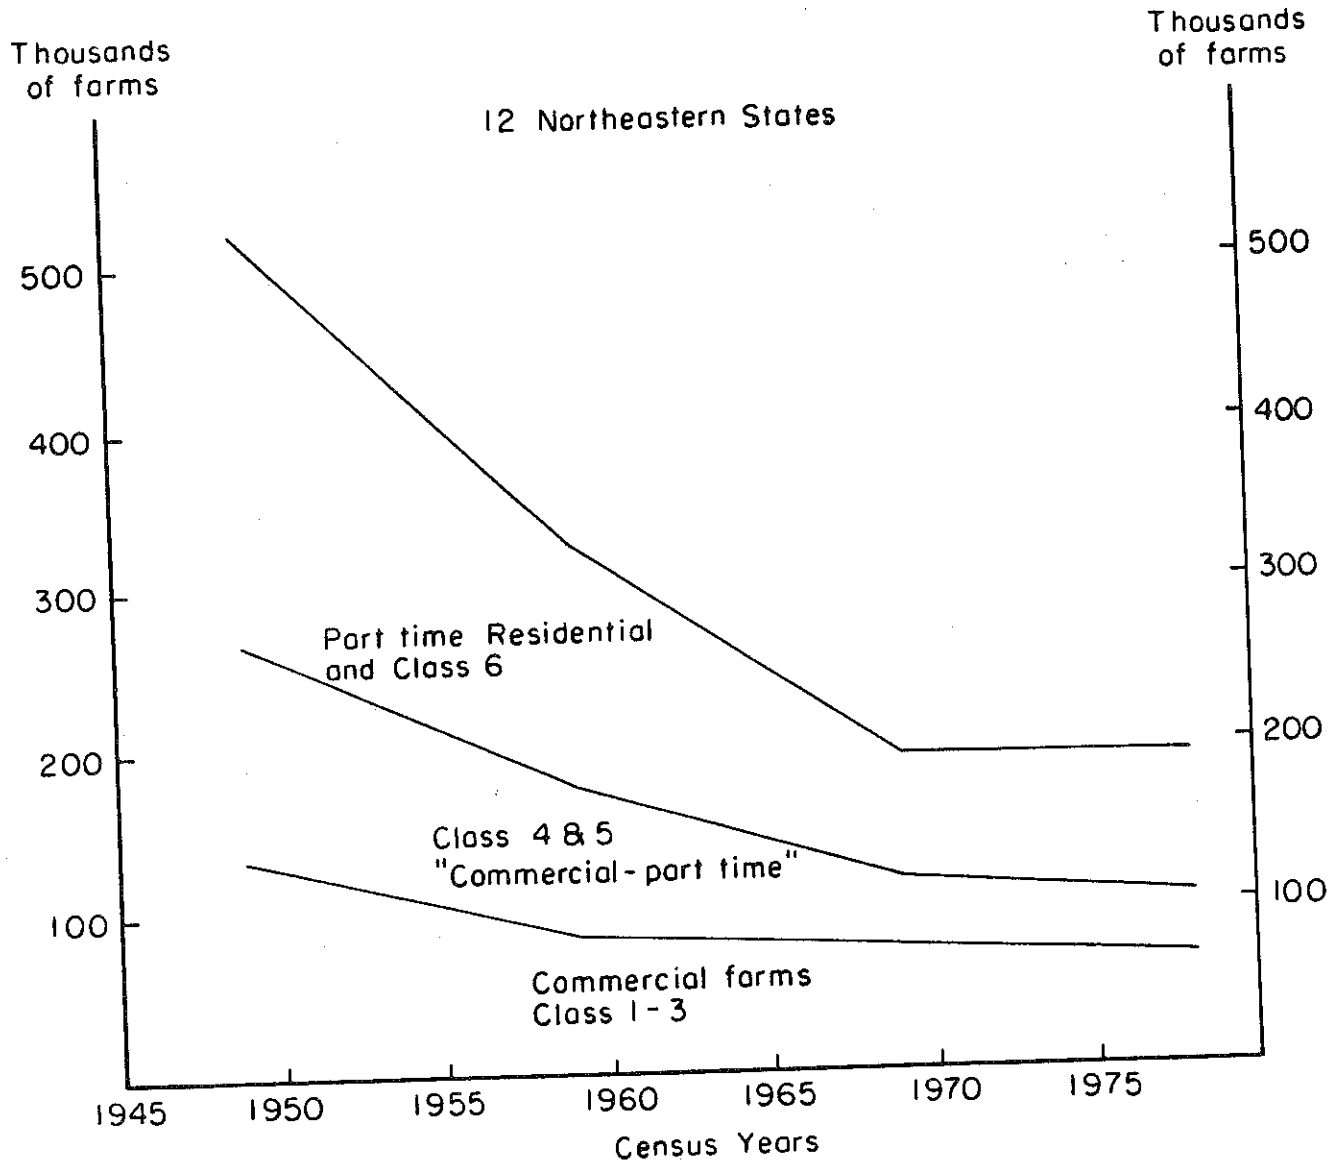

Figure 3. Decreases in farm numbers by Economic Class of Farm, 12 Northeastern States, 1949-1978

than 8 percent in 1978. The relative changes over the past 30 years are quite similar to those nationally. Commercial, full-time farms have been more stable in numbers than other groups. Very substantial reductions in numbers have occurred for the smaller, part-time and residential farms. Stability in numbers for all groups has been achieved during the last decade. Specific information for each of the Northeastern States from the census in 1978 is summarized in Table 5.

Table 5.

CLASSIFICATION OF FARMS BY TYPE
12 Northeastern States and United States, 1978

States	Part-time farms		Primary income from farming	All classes of farms*
	Sales less than \$5,000	\$5,000- \$19,999	Sales over \$20,000	
	-----number of farms----			
Maine	4,198	1,260	2,691	8,149
New Hampshire	1,965	575	736	3,276
Vermont	3,165	931	3,162	7,258
Massachusetts	2,861	1,270	1,740	5,871
Rhode Island	467	168	228	863

*Abnormal farms not included.

Source: Census of Agriculture, 1978

The foregoing examination of farm numbers and census statistics for 1949-78 has been developed to support classifying farms nationally into two major categories: (1) part-time and (2) full-time, commercial enterprises.

Further, because part-time farms make up so large a proportion of the total numbers and encompass such a wide range of situations, some further division is necessary both for description and analysis. The part-time residential units where agricultural sales are relatively unimportant to the family should be differentiated from the part-time farms where farming is more important either for beginning farmers at one end of the spectrum to older farmers retiring at the other.

Worker Equivalents in Farming

One approach to classifying farms into meaningful categories and differentiating part-time operations from full-time is to determine the worker equivalents used in farm operations. The concept of man equivalents or worker equivalents to measure size of business has been used in farm management from the beginnings of our discipline (7). It has been common to describe farms as one man or two man businesses (12, 13). Estimating worker equivalents used in farm operations is not difficult for either farmers or enumerators. Current reporting requirements for hired labor on commercial farms indicate that such estimates could be readily obtained on a regular basis from large businesses as well as smaller ones.

One approach to obtaining consistent data over time on two different groups of part-time farms and a size classification of commercial farms is presented in Table 6. Initially some combination of gross farm sales and worker equivalents used in farm operations would be necessary for the two categories of part-time farms. Particularly for individuals who are in ill health, partially disabled, or in their retirement years, farming activities may be the only things they do. But if the output that results is very small, say under \$5,000 of agricultural sales, then the worker equivalent expended in "standardized" terms would also be small.

Table 6. LABOR BASED SIZE DISTRIBUTION OF FARMS
Potential Definitions and Comparisons, United States

Annual worker equivalent used in farm operations	Description of farm type	Rough equivalent 1980 gross farm sales
<u>PART-TIME</u>		
0.00 - 0.24	Part-time, residential (mostly non-farm)	Under \$5,000
0.25 - 0.74	Part-time, (some commercial farm activity)	\$5,000 - 19,999
<u>COMMERCIAL, FULL TIME</u>		
0.75 - 1.49	Commercial, one worker	\$20,000 - 49,999
1.50 - 2.49	Commercial, two worker	\$50,000 - 99,999
2.50 - 3.49	Commercial, three worker	\$100,000 - 199,999
3.50 - 4.49	Commercial, four worker	\$200,000 - 299,999
4.50 - 10.49	Commercial, 5-10 worker	\$300,000 - 749,999
10.50 and up	Commercial, very large	\$750,000 and over

One advantage of worker equivalents used in farm operations as the primary method of classifying farms into groups is its stability of definition through time. Comparisons can be made between years. Inflation or a change in price level is not a problem as it has been with gross farm sales. The idea of describing commercial farm businesses as one worker or two worker farms is old and familiar. Establishing appropriate ranges of gross farm sales that are roughly equivalent to the number of workers per farm will be an important component of such a shift in emphasis at least initially. One of the surprises in studying available, historical data on farm size in the United States is the absence of data on labor units employed in farming either

in the census or USDA series (4, 13). Substantial efforts have been made to record information on hired labor. Consistent estimates of all labor used on individual farms, including family labor and the farm operator, are largely confined to farm management studies or farm record summaries in the various states.

An International Comparison

Part-time farming is an important component of rural living and agriculture in the United States as it is in most industrialized countries in the western world. In both Europe and Japan, part-time farms have been identified statistically and have been an important concern for public policy activity during the last two decades. The formal definitions for full-time and part-time farms are of some interest from a conceptual point of view and for purposes of international comparisons.

A full-time farm is defined as one in which no family member is engaged in any off-farm work for more than 30 days in the census year. If any family member, including the operator, himself, does off-farm work (30 days or more of employed work, or self employed business work of 50,000 yen or more annual income by the family), the household is classified as a part-time farm household.Part-time farm households are then divided by Japanese census statistics into two categories: Type I, households in which net farm income equals or exceeds off-farm earnings; Type II, households in which total off-farm earnings exceed net farm income. This subdivision is made on the basis of income dependency of the household, irrespective of the number of days worked off-farm or who was engaged in off-farm employment. (Kada)

While these definitions may not be directly applicable to American conditions, they do indicate how another nation has chosen to delineate different types of farms. Sources of income and family commitment to farming are of central importance. The need to differentiate part-time farms into two groups is also of interest. The magnitude of changes in numbers in the three classes between 1950 and 1980 is shown in Table 7.

Table 7. CHANGES IN FARM NUMBERS BY TYPE OF HOUSEHOLD
Census of Agriculture, Japan, 1950-1980

Year	Type of farm household			Total
	Full-time	Type I Part-time	Type II Part-time	
	<u>millions of farms</u>			
1950	3.09	1.75	1.34	6.18
1960	2.08	2.04	1.94	6.06
1970	.85	1.81	2.74	5.40
1980	.62	1.00	3.04	4.66

Source: Kada, Ryohei, "Trends and Characteristics of Part-Time Farming in Post War Japan," Geo Journal, Vol. 6:2, 1982.

In general the Type I and full-time farms are similar in the size of average land holdings (1.9 ha) and in net farm income. The Type II part-time farms have about 40 percent as much land in crops as the other two groups and the productivity per hectare is less than 50 percent of that on Type I part-time or full-time farms. These differences are a subject of public policy debate in Japan with respect to the efficiency of resource use, including land, family labor and capital.

Policy and Analysis

One reason for emphasizing the concept and definition of a farm producing unit and the need to differentiate part-time farms from those in the primary producing sector is to improve discussions of public policy and to provide a stronger basis for informed analysis. During the years since World War II more than 85 percent of saleable agricultural production has been produced by 2 million farms at maximum and less than 1 million in the

1970's, not the 5 million of the full census count or 2.4 million recently. When the media give the headlines to farming as many did in the spring of 1982, it is less likely that Time would write, "Millions of farmers are operating at severe losses" (April 12, 1982), especially if they knew there are less than one million farm operations which depend on farming for their primary income.

A clear demarcation of part-time from full-time farms will allow more careful consideration of public policy issues, or the lack of them, for the large number of families and the substantial amount of capital and natural resources controlled or operated by part-time farm families. The proposal to divide part-time farms into two groups (Table 6) follows a number of efforts by the professionals in Census to treat this diverse group in a more consistent and meaningful way. Those units which use less than 0.25 worker equivalents from all sources in farming and then sell less than \$5,000 of agricultural products constitute a relatively large number of families who rely primarily on nonfarm sources of income. Those farm units using 0.25 to 0.74 worker equivalents in farming include a number of subgroups of much greater interest and concern. Among this group may be some of the truly disadvantaged, where no member of the family has access to a good off-farm job. The farm resources available are not sufficient either in size or in quality to allow a decent living. Some of the most pressing rural poverty is likely to exist in this group. It is also likely to include a number of older farmers in some stage of retirement as well as all sorts of part-time commercial operations.

The key decision in defining farms is the breaking point between part-time and full-time or the primary producing sector from the rest. The suggestion of a lower limit of three-quarters of a worker equivalent may not

be low enough. Perhaps the lower limit for the primary producing units should be closer to 6 months of labor or 0.5 worker equivalents.

The line between primary production units, regardless of who owns or operates them, and the part-time sector is important. Conceptually a labor based measure appeals to me because it is a physical measure and one which farmers can estimate with reasonable knowledge and accuracy. Moreover, it makes farm units in this country much more comparable with others throughout both the developed and less developed world. It is my general observation that family farm businesses are the norm throughout most of the world. Land resources and capital are combined with labor in very different proportions in different societies. But one, two, three and four worker farms predominate most places in the world. Initially some combination of gross farm sales and worker equivalents could be used to draw the line with periodic adjustments in the gross sales figure built into the definition.

The need to understand what is happening on America's farms and what is being produced by different types and sizes of businesses is important to all of us. An argument for determining the labor used in farming as a descriptive measure of size of business has been advanced because of its advantages in making comparisons through time and across different types of farming. It is likely that the number of worker equivalents per farm and value added are more closely correlated than other measures of size. This is another reason for placing more emphasis on a labor based classification of farms.

Net Farm Income

One of the most important agricultural statistics calculated nationally is net farm income. This is an aggregate figure representing returns to all farm resources. Estimates are also made for different sizes of farms based on agricultural sales. The economic status and well being of farm families

is considered by combining off-farm sources of income with net income from farming. New procedures for calculating net farm income were instituted by the Economic Research Service in 1980. These procedures follow the general methodology used in other sectors of the economy, where the operator's dwelling and household accounts are separated from business activities (ERS Statistical Bulletin 674).^{1/}

A summary of these annual estimates for the period 1960-1980 is presented in Table 8. Before 1960 estimates of off-farm income for farm families were not made. The series has been deflated by the CPI to allow comparisons in terms of the purchasing power of family income. The aggregate net income from farming shows no clear trend over the 20 year span, when price level is taken into account. Clearly net income has been much more volatile in the 1970's than in the 1960's, but this is mostly variation around a flat trend line rather than a clear downturn as some have suggested.

In contrast off-farm income sources have become a more important component of total family income in each 5 year period. Off-farm income is more stable and there is a measurable trend component. The data base for the two series is quite different. Net income from farming is monitored in detail with estimates constructed for individual states. Cash receipts and cash expenses are calculated using alternate sources of information. Substantial effort is put into developing careful and accurate data sets. Off-farm income estimates receive much less attention and are based on a very limited data base.

^{1/} A discussion of procedures used and important definitions comparing the old and new accounting methods are presented on pages 1-9 in ERS Statistical Bulletin 674.

Table 8. INCOME OF FARM OPERATOR FAMILIES
Constant 1967 Dollars, United States, 1960-80

Year	Net income from farming	Off-farm income	Total family income	Total family income per farm
	1967=100			
	<u>millions</u>	<u>millions</u>	<u>millions</u>	
1960	\$12,985	\$ 9,563	\$22,548	\$ 5,690
1961	13,345	10,227	23,571	6,163
1962	13,316	10,932	24,247	6,567
1963	12,835	12,017	24,853	6,957
1964	11,294	12,526	23,820	6,890
1965	13,650	13,468	27,118	8,080
1966	14,362	14,282	28,644	8,794
1967	12,339	14,495	26,834	8,486
1968	11,825	14,843	26,668	8,684
1969	13,017	15,129	28,147	9,382
1970	12,168	14,959	27,126	9,199
1971	12,063	15,522	27,585	9,505
1972	14,896	16,453	31,350	10,962
1973	25,056	17,850	42,906	15,199
1974	17,691	17,953	35,644	12,617
1975	15,183	17,030	32,213	11,642

The final column in Table 8 presents real family income per farm, an important measure of average levels of income for farm families. Even though net income from farming has not increased in the aggregate, farm numbers have declined and net farm income per farm has increased. This rather straight-forward idea is often lost when comparisons are made between aggregate net income in 1980 and earlier years.

Family Income by Size Class

One of the ways of examining the relative position of farm families compared to other groups in society is to compare per capita personal and disposable incomes for farm and nonfarm populations. Such series have been calculated since 1934 (ERS Statistical Bulletin 674). In the 1950's farm income as a percentage of nonfarm income per capita ranged between 47 and 64 percent. By the 1960's the range was 53 to 73 percent. In the 1970's the range was from 73 to 109 percent. Over the three decades the trend has been clearly upward and some approximation of greater parity has been achieved. But every average has a distribution of incomes that lies behind it. Serious analysis and understanding of what has been happening requires study of the distributions themselves.

It is here that some permanent mechanisms to decompose farm numbers into a small number of meaningful groups would be most helpful. Estimates of farm family income from all sources classified by amount of agricultural sales is available for the years 1960-1980 (15). Data for 1980 are presented in Table 9. The size classes have been further aggregated into three groups to roughly approximate the categories proposed earlier. As the averages indicate, off-farm income provides an important component of family living in every size category including the largest commercial farms.

Table 9. FARM FAMILY INCOME BY FARM SIZE
USDA Estimates, United States, 1980

Value of agricultural sales	Average net farm income	Average off-farm income	Average farm family income	Farm income as a percent of total
<u>Commercial, full-time</u>				
\$100,000 and over	\$33,972	\$12,922	\$46,894	72
40,000 - 99,999	16,674	7,922	24,596	68
20,000 - 39,999	8,280	9,358	17,638	47
Group average	19,325	9,839	29,164	66
<u>Part-time, commercial enterprises</u>				
\$10,000 - 19,999	4,299	12,847	17,146	25
5,000 - 9,999	2,512	16,768	19,280	13
Group average	3,342	14,947	18,289	18
<u>Part-time, residential</u>				
\$2,500 - 4,999	1,582	20,156	21,738	7
Under \$2,500	1,821	20,242	22,063	8
Group average	1,723	20,207	21,930	8
All farms	9,002	14,820	23,822	38

Source: USDA, ERS Statistical Bulletin 674, September 1981, pp. 106.

The two lowest averages for farm family income are in the \$20,000-39,999 and \$10,000-19,999 sales classes. These are likely to be the groups with substantial variability in levels of poverty, family net worth, and reliance on farming for family living. In particular there is need to improve and enlarge the basis for estimating off-farm income for these groups if further analysis leading to policy recommendations is to be based on these

statistics. This is one area where a re-examination of priorities might well lead to more resources being spent on an existing program at the expense of other data series where pressure for policy related analysis is less strong.

Summary Comments

1. This paper argues that farms as business units should be divided into three basic categories:

(a) full-time, commercial units (the primary producing sector for agricultural production where 0.75 or more worker equivalents are employed in farming)

(b) part-time farms - commercial enterprises (where agricultural sales are important but family living comes primarily from off-farm sources and 0.25 to 0.74 worker equivalents are employed in farming)

(c) part-time, residential farms (where less than 0.25 worker equivalents are employed in farming and agricultural sales are not an important source of family income).

2. The USDA and Bureau of Census, with the advice of representatives from appropriate professional associations, should establish a set of clear definitions for the three categories of farms based on physical criteria which can be continued over a span of years.

3. Substantially less emphasis should be given to describing farms on the basis of gross agricultural sales because inflation makes comparison of such size distributions through time very difficult and because value added for different types of farming activity are so divergent.

4. Estimates of net income from farm and off-farm sources are important data series. This is particularly true for the two categories of part-time

farms. Monitoring income from off-farm sources, particularly for the largest farms employing 4 or more worker equivalents, has much lower priority.

5. The concept of a farm as the primary business unit producing crop and livestock products is not obsolete. Definitions must allow for a wide range of organizational forms from individual proprietorships to cooperatives and corporate entities. The challenge is to insure that this dynamic sector is constantly monitored and that our data systems accurately reflect change as it occurs.
