A Statutory College of the State University  
Cornell University, Ithaca, New York, 14853

It is the policy of Cornell University actively to support equality of educational and employment opportunity. No person shall be denied admission to any educational program or activity or be denied employment on the basis of any legally prohibited discrimination involving, but not limited to, such factors as race, color, creed, religion, national or ethnic origin, sex, age or handicap. The University is committed to the maintenance of affirmative action programs which will assure the continuation of such equality of opportunity.

Factors Affecting the Location of the U.S. Biotechnology Industry

William B. Magrath\*

\*William B. Magrath is a Senior Research Support Specialist, Department of Ag. Econ., Cornell University.

An approach more frequently seen in the literature on location economics is to identify the site specific factors that most heavily contribute to profitability. This led to the development of the concepts of ubiquities, transfer orientation, and weight gaining/losing activities. For certain industries, the significance of particular raw materials, such as wood and water for pulp and paper production, can be readily seen. Less basic industries, utilizing a wider array of inputs, require more detailed study to identify the characteristics of desirable locations. Budgeting techniques have also been used for predictive and planning purposes but are only appropriate for mature industries with relatively uniform products and processes.<sup>3/</sup>

An approach that has received wider use is to survey managers with questions about the factors that were relevant to their location decisions. Examples of these studies are the classic study by Mueller, et al, and studies by Mandell, and Schmener. A survey of high technology electronics firms was also conducted by Premus for the Joint Economic Committee of Congress.

While subject to numerous weakness (sampling and respondent bias, poor design and administration, etc.) these surveys probably provide the best information available on the motivations behind firm location decisions. Generally, the findings of these studies are presented in terms of the relative importance of various factors (availability of low cost labor, access to raw materials). Authors typically go on to evaluate the suitability of a region(s) for particular industries or to suggest policies to improve the attractiveness of a region. While little can be found in the findings of these surveys to contradict the hypothesis that firm managers seek profit maximizing locations, they do indicate the importance of other factors. Most important, and most often neglected in other studies and in discussions of policy implications, is the observation that the location of most firms results from the personal circumstances of the founder. This is especially true of single location operations and relatively new firms. Specifically, firms tend to be located where they are because that is where the entrepreneur lived at the time the firm was started (Mueller, et al., pp. 4, 13-16).

It is difficult to compare the relative importance of other location factors as revealed by the different surveys reviewed for this paper. The surveys were conducted in slightly different ways and although similar questions were asked, wording may have differed slightly. The different time periods when the surveys were conducted is illustrated by the fact that in early work energy costs were not specifically considered. Nonetheless, review of this literature suggests that the estimated importance of key location factors is relatively consistent across surveys. High technology companies appear to possess slightly stronger preferences, although their relative ranking of different factors is quite similar to that of general manufacturing companies.

Other techniques to study location patterns involve the use of aggregate data and a variety of statistical procedures. Examples of these studies include a recent study of high technology industry by Glasmeier, Hall and Markosen (GHM). It provides an example of these approaches and of the difficulty of applying elaborate statistical techniques. Using an extensive database developed from U.S. Census sources, GHM developed measures to represent variables thought to be associated with plant location. For example,

they used county level wage rates, unionization rates and area unemployment rates to represent labor supply conditions. In all they used 20 measures to represent five sets of variables. Using stepwise linear regression they sought the set of measures that best explained the distribution of high technology employment. Despite the extensiveness of their data set, GHM were unable, as are most statistical location studies, to reach strong conclusions on the determinants of high technology activity.

In sum, there is no entirely satisfactory methodology for the analysis of location decisions. The choice of research technique needs to be made in the context of the problem being studied and the information that is sought. For example, budgeting procedures are probably the best approach to specific location decisions for individual firms, while statistical procedures are applicable to testing hypothesis about well-defined industries. Given the explanatory nature of this research, it was most appropriate to use the survey technique to develop a general understanding of the factors relevant to biotechnology decisions.

### Survey Methodology and Results

In carrying out the objective of this research, the first issue that needed to be considered was the selection of firms to survey. There is no generally accepted statistical definition of the biotechnology industry. The Standard Industrial Classification (SIC) system groups into several distinct categories (Basic Chemicals, Drugs, Food and Kindred products) firms that would be generally considered as being involved with biotechnology. Unfortunately, these categories also include firms that would not be considered as biotechnology firms. The reason for this is that the defining characteristic of the biotechnology industry is the use of living organisms, biological agents or novel biological systems in industrial production. The SIC and other widely used classification systems, on the other hand, are based on a firm's primary output.

In order to obtain a listing of firms that are actively involved in commercial use or development of modern biotechnologies I examined a number of sources. Ultimately, the most satisfactory listing was thought to be the International Biotechnology Directory, 1984 (Coombs, 1984) which provides names, addresses and short descriptions of 731 companies. We combined this list with one published by the Office of Technology Assessment (1984). We initially surveyed the resulting list of companies to obtain publicly available financial information. Despite its being the best available listing of biotechnology firms, several firms indicated no involvement in biotechnology and 52 firms could not be contacted by mail. After removing those firms from consideration a final list of 696 firms remained in the present sample.

The firms surveyed included a wide variety of biotechnology involvements. Major corporations with interests in brewing, food processing and pharmaceuticals were included as well as small companies working with developing technologies and others manufacturing equipment and providing consulting services. Although it is impossible to know, it is likely that the firms surveyed represent a substantial portion of the U.S. biotechnology industry. The geographic distribution of firms sent surveys is shown in Figure 1. Consistent with what is widely believed about the biotechnology industry there is a concentration of firms in California and around Boston, Massachusetts. Somewhat surprising is the

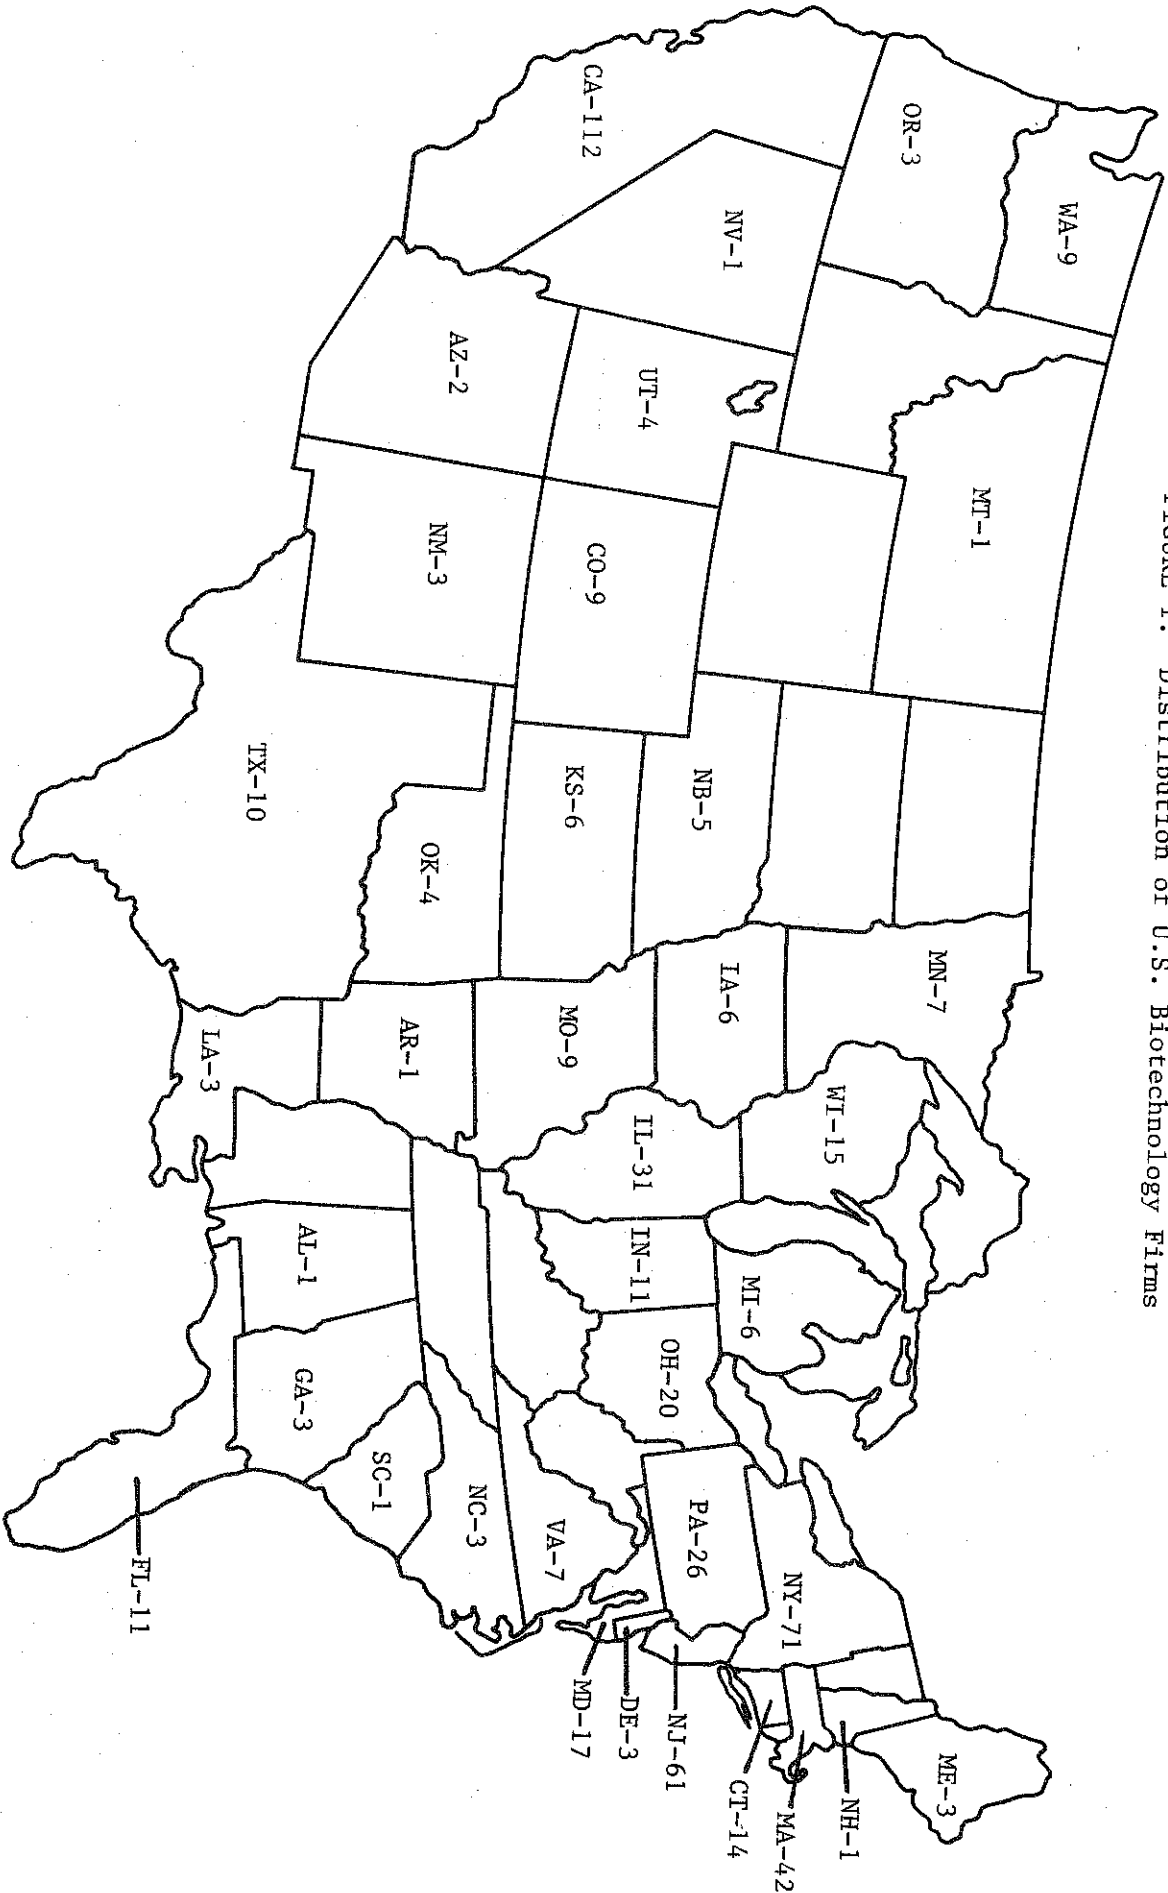

FIGURE 1. Distribution of U.S. Biotechnology Firms

relatively large number of firms (71) located in New York, making it the second ranking biotechnology state as measured by firm numbers. New Jersey with 61 firms ranks third in the presence of biotechnology activity. The addresses given by firms makes it difficult to know to what extent the distribution shown in Figure 1 represents "corporate headquarters" versus production facilities or research and development laboratories.

Based on the survey instruments used for other industries (see above) a questionnaire was prepared. In addition to probing for information on the relative importance of various location determinants, the questions were designed to elicit information to help understand specific issues related to the biotechnology industry. For example, a set of questions were related to the importance of universities as attributes of regions. The questionnaire is reproduced in appendix 1.

Of the 696 firms surveyed in Fall 1984, completed returns were received from 111. An additional 11 surveys were returned by the post office as undeliverable. There was no follow-up with non respondents. Of those receiving surveys, there was a total return rate of 16%. Response covered a range of geographic areas. The greatest number of responses were received from California, followed by New Jersey, Pennsylvania, Massachusetts, and New York. In all, responses were received from firms in 27 states. The geographic distribution of responding firms was generally consistent with the distribution shown in Figure 1.

Forty-four of the firms indicated that their major activity was research and development. Twenty-nine and fifteen said that manufacturing and pharmaceuticals, respectively, were their major product lines. Eight firms listed agricultural products, only 4 firms indicated any activity in food processing. The three major enterprises of respondents are summarized in Table 1.

The majority (62%) of the responses were from privately held companies. Fifty percent were privately held corporations, twelve percent were sole proprietorships or partnerships, the rest (38%) were publicly held corporations. The average company had been in business for 23 years, however, 51

\*Percentages do not add to 100 because some firms did not indicate second and third product lines.

percent had been started after 1970. The median number of employees was reported as 50 and median annual sales were \$1 million. The presence of several large firms in the sample accounted for average sales and employees of \$282 million and 1,803, respectively.

It has been shown that there are considerable economics of scale in the production of at least some biotechnology products (Kalter et al.). Combined with the generally light weight of biotechnology products this argues for relatively few plants serving dispersed markets. To examine this we asked respondents to describe their firms primary market area. Results are shown in Table 2 for current sales and for 1989. As can be seen almost three quarters of the firms currently serve international markets with most of the remainder serving national markets. No firms described their markets as focusing at the state or local level.

(% of Responding Firms)

	Current	Forecast (1989)
Local	0	0
State	0	0
Regional	3	1
Nationwide	26	26
International	71	73

We also asked respondents to indicate the importance of a variety of factors that are often proposed as affecting location. These responses are shown in Table 3. By far the most important factors are the availability of professional employees and technicians which were described as critical by 34 and 26 percent of firms respectively. These were followed in importance by business climate, state and local taxes, cost of living and cultural amenities. Factors frequently described as unimportant were proximity to markets (57%), proximity to raw materials (56%), access to venture capital (46%) and academic institutions (60%). These results seem plausible in light of the human capital intensive nature of the biotechnology industry, and national and international markets for products, inputs and capital. The low importance attracted to universities suggests that managers perceive that new scientific results related to their companies move easily and are readily available regardless of location.

Table 4 compares the results of this survey with surveys of the location preferences of firms in other industries. The comparison indicates that, in general, the ranking of factors is similar, but that there are several important differences. Labor availability and cost, tax climate, and access to raw materials appear to have similar weight across industries. Biotechnology firms appear considerably more sensitive to Business climate and access to venture capital than firms in other industries (despite the fact that access to venture capital was generally unimportant to biotechnology firms). Local

a/ Non respondents mean rows may not total to 100%.

academic institutions are more highly valued by biotechnology firms than general manufacturing firms, but less than by the high technology electronic firms surveyed by the Joint Economic Committee.

Sixty percent of the firms surveyed indicated that state and local government incentives had significant impact on location decisions (Table 5). There was little consensus, however, on the effectiveness of various types of location incentive programs. Receiving most interest were low interest loans, investment tax credits, and property tax abatement (Table 6).

Investment Tax Credits	46	51	3

Because of the emphasis that is often placed on Universities and research facilities as being promoters of high tech industry, respondents were also asked to indicate the ways in which universities are important attributes of regions. The two most often cited as very important were as sources of future employees and for library resources. Teaching opportunities for employees, access to laboratories and cultural activities were generally considered unimportant (see Table 7). Another indication of the way in which universities are related to the location of biotechnology firms is the finding that one third of the founders of responding firms had previously been associated with a local university.

Of the 111 firms that responded, 58 continue to operate in the same city in which operation first started, and 91 were located in the original state. In addition, 35 were founded in and continue to operate in the city in which the founder lived prior to starting the company. Sixty-seven of the firms were still located in the home state of the founder. Further, as firms grow, most (76%) plan to expand their current facilities (Table 8).

Table 7. Significance of Universities to Biotechnology Firms

Expansion of Current Facilities	76

The fact that biotechnology firms generally remain in the area in which they were founded is consistent with findings from other industries. This, together with the indicated importance of business climate and the fact that firms tend to be initially located near their founders home, indicates the highly individual and personal nature of location decisions. In general, the factors that affect biotechnology location are not different from those that affect location by manufacturing firms in general.

#### Summary and Policy Implications

This research suggests a number of important considerations for those interested in the local economic development potential of biotechnology. In general, unlike firms heavily dependent on site specific resources, biotechnology firms seem to be successfully located in a wide variety of places. Similar to other industries biotechnology firms are attracted to

regions by conducive business and social climates. This suggests that any individual region is unlikely to have a natural predisposition to be a major center for biotechnology. Agglomerations that do occur will almost certainly be due to a regions capacity to successfully foster (formally or informally) an entrepreneurial climate. Further, the growing competition among states and localities to attract these firms reduces the chance of any one region becoming dominant in biotechnology.

The theory that no individual region is likely to capture a large share of the benefits of high tech development also has implications for the financial support of research. Because research results have the character of public goods, it will be difficult to prevent technology developed in, say, New York from being commercialized in other states. To some extent this can be managed by the development of policies for the acquisition of patents and their use to further regional development objectives. More generally it is another justification for federal support of high technology research and for state and local pressure to that end.

Before significant public resources are devoted to attracting new high technology firms, it is, however, important to realize that there is no strong evidence that the presence of these industries contributes significantly or uniquely to the achievement of regional development objectives. The Office of Technology Assessment has found that established traditional industries are likely to continue to be the source of the greatest absolute growth in employment opportunities (U.S. Congress, July 1984). The regions most likely to benefit from rapid technological change will be those in which traditional industries utilize and adopt new methods to improve efficiency and promote growth.

According to survey respondents the most important characteristics of regions for biotechnology companies is the availability of skilled labor. Respondents also indicated that the role of universities in providing skilled labor is an important way in which universities contribute to the appeal of a region. Nonetheless, universities and other academic institutions are not identified by managers as being important attributes of regions per se. However, it is also true that the industry is, in fact, clustered in a number of states (California, New York, Massachusetts, Wisconsin) that are noted for quality research universities. Additionally, one-third of the founders of responding firms were associated with local universities.

Finally, this research suggests that there should be no conflict between policies promoting the development of a biotechnology industry and the development of traditional industry. The preferences of biotechnology managers are quite similar to those in other industries. Thus, policies and programs that broadly encourage business expansion and entrepreneurial activity should be the prime focus of local and regional developers.
