INCOME AND DIETARY CHANGE: INTERNATIONAL COMPARISONS USING PURCHASING-POWER-PARITY CONVERSIONS

**Thomas T. Poleman
and
Lillian Thomas**

It is the policy of Cornell University actively to support equality of educational and employment opportunity. No person shall be denied admission to any educational program or activity or be denied employment on the basis of any legally prohibited discrimination involving, but not limited to, such factors as race, color, creed, religion, national or ethnic origin, sex, age or handicap. The University is committed to the maintenance of affirmative action programs which will assure the continuation of such equality of opportunity.

INCOME AND DIETARY CHANGE: INTERNATIONAL COMPARISONS USING PURCHASING-POWER-PARITY CONVERSIONS

by
Thomas T. Poleman
and Lillian Thomas

The effect of income growth on dietary composition is well recognized. Among the poorest people, be they individuals or nations, diets tend to be composed principally of starch: wheat, rice, potatoes, cassava, and the like. This is so because of the cheapness of these starchy staples, whether expressed as market price or production cost. Far less land and far less labor are needed to produce a thousand calories of energy value in the form of the starchy staples than in the form of any other foodstuff. As wealth increases the contribution of these starchy foods falls and a still largely vegetarian diet becomes more diversified. Then products of animal origin--meat, eggs, and dairy products--loom larger in the diet until, as in the wealthy countries of the industrialized West, they supply between 33 and 40 percent of total caloric availabilities. This dietary evolution seems to be universal, although the exact modifications which take place will vary in accordance with local circumstances such as market availability and price and cultural considerations such as religious taboos. But if income can be expressed in reasonably comparable terms, the experience of wealthier countries can provide a fair indication of what their poorer neighbors can expect to undergo as they develop.

This paper illustrates the course of diet change in countries representing the bulk of mankind. Plotted are changes in the percentage of calories contributed by the starchy staple foods (the starchy staple ratio), by products of animal origin, and total per capita energy availabilities per day. The latter figure is frequently termed "consumption," but is not. It represents the supply of energy available for human consumption, and appreciable losses occur between it and what is actually eaten. "Availabilities," "disappearance," or "apparent consumption" are more accurate descriptions.

The figures are averages for the years 1984-86 and earlier and are taken from the latest compilation of food balance sheets published by the Food and Agriculture Organization (FAO) of the United Nations (1991) and are in no sense new. What are new here are the income figures used. So that some comparability may be achieved between nations, it is necessary to convert incomes to a standard currency, in this case 1985 US dollars. The conventional practice is to convert other currencies into dollars using the prevailing exchange rates. But such a conversion does not necessarily reflect actual purchasing power; recent work has shown that most developing countries have actual incomes several times that implied by the exchange rate conversion.

The reason market exchange rates are imperfect converters of income into a common currency is that while such rates tend to equalize prices of internationally traded goods, big differences can and do remain in the prices of nontraded goods and services. Developing countries tend to have cheaper services--domestic help is the classic example--than developed ones and countries in the former Soviet bloc kept food, housing, and energy artificially cheap. Converting these countries' GDP using market exchange rates therefore has the effect of systematically understating their real output and income.

The International Comparison Program (ICP) sponsored by the United Nations attempts to correct for these biases by collecting and comparing prices for over 1,500 commodities, services, and labor inputs representing the universe of items priced in a country. The price comparisons that emerge are then aggregated into an overall purchasing-power-parity (PPP) figure used to relate income to a common currency unit (Summers and Heston 1991). ICP estimates of per capita GDP converted into US dollars using PPP conversions are available in several forms. They have appeared since 1989 among the world development indicators appended to the World Bank's annual *World Development Report*. In May 1993 the IMF began publishing regional aggregates in its quarterly *World Development Outlook*. The most complete source, however, is the Penn World Table (PWT), an annex to Summers and Heston (1991) available from the National Bureau of Economic Research on a personal computer diskette, or through the Internet. The version of that table used here, PWT (Mark 5.5) was released on 15 June 1993, covers the years 1950 through 1990 for most countries, and has 1985 as the base year.

The picture the PPP conversions paint of the global economy is strikingly different from that conveyed by using market exchange rates (IMF 1993). The developing countries' share of world output circa 1990 as calculated by the IMF jumps from 18 to 34 percent, while that of the industrialized countries drops from 73 percent to 54. (The so-called countries in transition account for the remainder.) China becomes the world's second or third biggest economy and India moves up to fifth place. Some country comparisons as of 1985 follow (PWT5.5 1993; World Bank 1987):

	Per Capita Income (\$US 1985)	
	GNP	GDP
	<u>Market exchange</u>	<u>Purchasing power parity</u>
India	270	1,116
China	310	1,811
Ghana	380	759
Egypt	610	1,859
Thailand	800	2,422
Brazil	1,640	3,951
Venezuela	3,080	6,037
Singapore	7,420	8,153
Canada	13,680	15,695

In all instances the PPP conversion points to per capita incomes considerably above those suggested by exchange rate conversions, typically by a factor of three or four among the poorest countries. As countries become wealthier (and more involved in the global economy), the differences between the two conversions lessen.

The impact that use of the two conversion procedures has on the income/dietary change relationship is shown in Figure 1. The three charts on the left show GDP per capita using PPP conversions, those on the right market exchange rate conversions of GNP per capita. To facilitate comparison income is plotted as a percentage of that prevailing in the United States. These base figures are almost the same: per capita GDP--\$16,559; per capita GNP--\$16,690.

It is apparent that the principal effect of using PPP conversions is to diminish the slope of the curves in the low-income range, a not unexpected finding. Incomes of about a fourth those prevailing in the United States, say \$4,000 in 1985 terms, are sufficient almost everywhere to complete the dietary transition if exchange rate conversions are used, whereas roughly double that is needed if PPP figures are employed.

Also apparent is the degree to which operation of the dietary transition differs from one part of the world to another. Because food was heavily subsidized in the former Soviet bloc, rather lower incomes (by either conversion) were needed to support high intakes of livestock products than was the case in the West.

Japan, Hong Kong, and Singapore are the Far Eastern countries with the highest per capita incomes. Whereas daily apparent consumption of energy levels out at \pm 3,500 kilocalories in the West, the figure is more like 2,800 in the Far East. This presumably reflects smaller body size, but also probably reduced wastage, particularly of animal fats in the cooking process. At any given income level animal products contribute a significantly lower percentage of dietary energy in Japan, Hong Kong, and Singapore than in the West, and the starchy staples more.

Such regional differences are more clearly evident in Figure 2, in which are plotted individual country trends for the years 1964-66, 1969-71, 1974-76, 1979-81, and 1984-86. The income figures are for the mid-year of these averages and are PPP conversions expressed in constant 1985 US dollars. The hand-fitted trend lines from Figure 1 are reproduced in the individual panels.

Developed Countries. That dietary change in Japan has followed a course different from the other developed countries is obvious in the panels on the extreme left. At any given income level the percentage of calories from animal products is appreciably lower than would be expected and the starchy staple ratio higher. A number of explanations have been offered for this behavior, but I expect the most important one is the high price of food in Japan. That the domestic price of rice ranges between six and eight times that prevailing on the world market is well known, and to purchase animal protein in a Tokyo restaurant is to risk financial as well as digestive distress.

While the starchy staple ratio seems destined in the Western developed countries to drop to the neighborhood of 21-23 percent, there is conflicting evidence as to what the final percentage contribution of animal products will be. Denmark--where dairy and fishery products loom particularly large--is clearly an anomaly at 45 percent. But will the substitution of vegetable for animal fats in the diet bring it to the 33-34 percent range found in North America, or will it remain at the 37-39 percent level prevailing in the principal European countries?

East and Southeast Asia. It was once thought that the anomalous course of dietary change in Japan vis-a-vis the West was a reflection of the rice-based character of Japanese cuisine. That this may not be the full explanation is suggested by the experience in the other East and Southeast Asian countries charted in the next set of panels. At comparable income levels the percent of calories from animal products is higher in both Singapore and Hong Kong than in Japan and the starchy staple ratio lower. But the behavior charted for East and Southeast Asia does point to several departures from the Western pattern. Daily per capita disappearance of energy would seem to level out everywhere about 700 kilocalories below the Western average and the pervasive role of rice cannot be denied: in both Singapore and Hong Kong the decline in the starchy staple ratio appears to stop at around 38 percent, while the contribution of animal products seems to plateau in the neighborhood of 30 percent. Otherwise the experience in East and Southeast Asia is a telling confirmation of the impact rapid economic growth has on dietary change.¹

South Asia. Incomes are still too low in the South Asian countries plotted for us to know whether the East and Southeast Asian pattern will be replicated there. Because of similar body size apparent consumption of energy may well level out at the same \pm 2,800 kilocalorie level, but the prevalence of taboos against the eating of meat, particularly in India, will doubtless play a confounding role. For clues, one must look to consumption surveys, but the differences evident in the percentage contribution of livestock products to the Indian and Pakistani diets are probably significant. At similar income levels the percentage in India is about half the figure in Pakistan.

Southwest Asia and North Africa/Latin America. In Latin America and the predominantly Muslim countries of Southwest Asia and North Africa the Western model would appear to be holding. The substitution of livestock products for starchy staples would appear on course and in the wealthier countries average per capita daily disappearance is approaching 3,500 kilocalories.

East and West Africa. Only data for 1964-66 and 1984-86 are plotted in the panels for East and West Africa. It is not just that the figures are of questionable accuracy; incomes have grown so little and the changes in diet have been so modest that to show the intervening years would serve only to obfuscate. About all that can be said is that the dietary transition has hardly begun in this unfortunate part of the world.

¹ Provisional data for 1990 for Japan and Hong Kong show little deviation from the trends noted through 1985:

	<u>Japan</u>	<u>Hong Kong</u>
PPP GDP/capita (\$US 1985)	14,836	14,410
Energy availabilities/capita (Kcal)	2,926	2,857
Percent calories from animal products	21.2	30.0
Percent calories from starchy staples	42.4	36.0

TECHNICAL NOTE

Obtaining the Penn World Table

An IBM-PC compatible 3.5 disk with the tables and a copy of the *Quarterly Journal of Economics* article are available from:

Publications Department
National Bureau of Economic Research (NBER)
1050 Massachusetts Ave.
Cambridge, MA 02138

Please enclose a check for \$US5 (US and Canada) or \$US15 (other).

The files may also be obtained from an anonymous FTP server at the NBER without charge by those with Internet access. A copy of the *QJE* article will still be required to make use of the data. The files available from FTP from directory/pub/pwt55 on nber.harvard.edu are:

<u>File</u>	<u>Bytes</u>
PWT55.ASC	1365300
README.DOC	4646
DESCRIP.DOC	11451

PWT55.ASC, the main data file, is an ASCII file. The data are provided in successive country blocks: the rows refer to years and the columns refer to variables.

An electronic mailing list devoted to discussion of the Penn World Table is available to any person capable of receiving Internet mail. To subscribe send the one-line message:

SUB PWT-L firstname lastname

to listserv@nber.harvard.edu, substituting your own first and last names for firstname and lastname. Do not place your email address in the body of the message. Subscribers to the list will receive timely notice of new data and may post questions and comments for the other members of the list to see.

Dietary indicators are: Kcal--per capita daily energy availabilities; SS (%)--percent of calories from starchy staples; Animal (%)--percent of calories from animal products, and are calculated from FAO. 1991. *Food Balance Sheets, 1984-86 Average*. Rome.

Purchasing-power-parity GDP per capita figures are expressed in 1985 U.S. dollars and are from Penn World Table (Mark 5.5). 1993. Annex to Summers, Robert and A. Heston. 1991. "The Penn World Table (Mark 5): An Expanded Set of International Comparisons, 1950-1988." *Quarterly Journal of Economics*. May.
